# TSGs

# TSGs

Given an *input corpus* of parsed sentences, TSGs define:

- how to extract from it a bag  $T$  of *elementary trees*
- how to combine them to form (*new*) *parse trees*

Given a new sentence our TSG can produce possibly many parse trees yielding the sentence. We need to select only one (*disambiguation*).

# Stochastic TSGs

STSGs define a probabilistic model over the possible parse trees which can be produced by the grammar.

For every parse tree  $t$ ,

$$d : \tau_1 \circ \tau_2 \circ \dots \circ \tau_n = t$$

$$P(d) = F(\tau_1) \cdot F(\tau_2) \cdot \dots \cdot F(\tau_n) \text{ where } F(\tau) = \frac{f(\tau)}{\sum_{\tau' \in r(\tau)} f(\tau')}$$

$$d_1, d_2, \dots, d_m = t$$

$$P(t) = P(d_1) + P(d_2) + \dots + P(d_m)$$

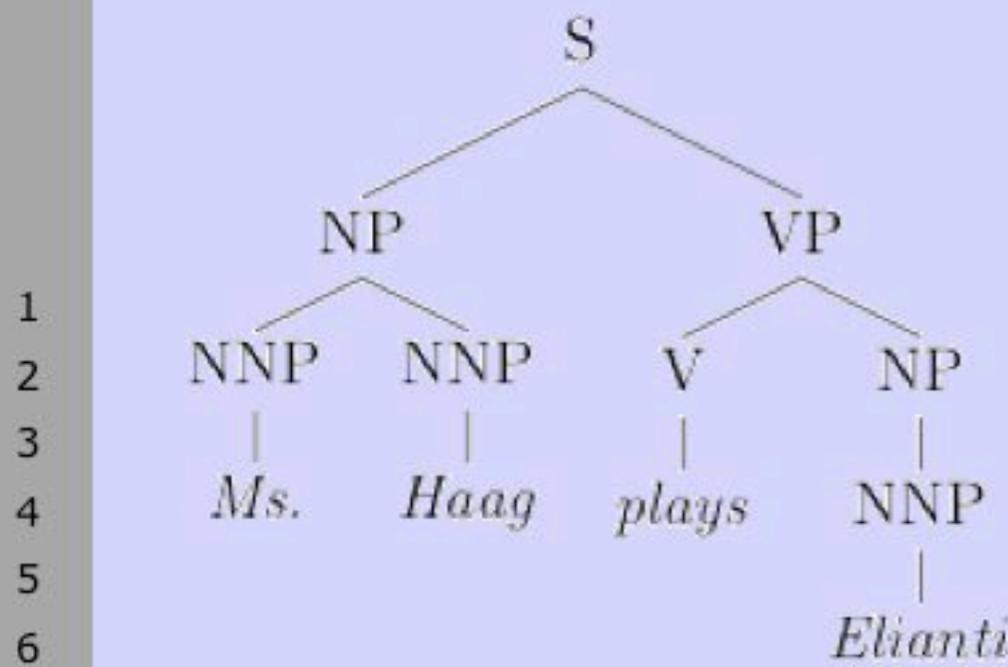

If we have a test sentence, we generate all possible parse trees yielding that sentence and select the one with max probability.

### Hill climbing strategy

- starts from a given head annotation (i.e. random)
- aims at reducing the uncertainty of the structures which can be associated to each lexical item

### Entropy (Information Theory)

discrete stochastic variable  $\tau_l$

taking  $n$  possible values  $\tau_{l_1}, \tau_{l_2}, \dots, \tau_{l_n}$

with probabilities  $p(\tau_{l_1}), p(\tau_{l_2}), \dots, p(\tau_{l_n})$

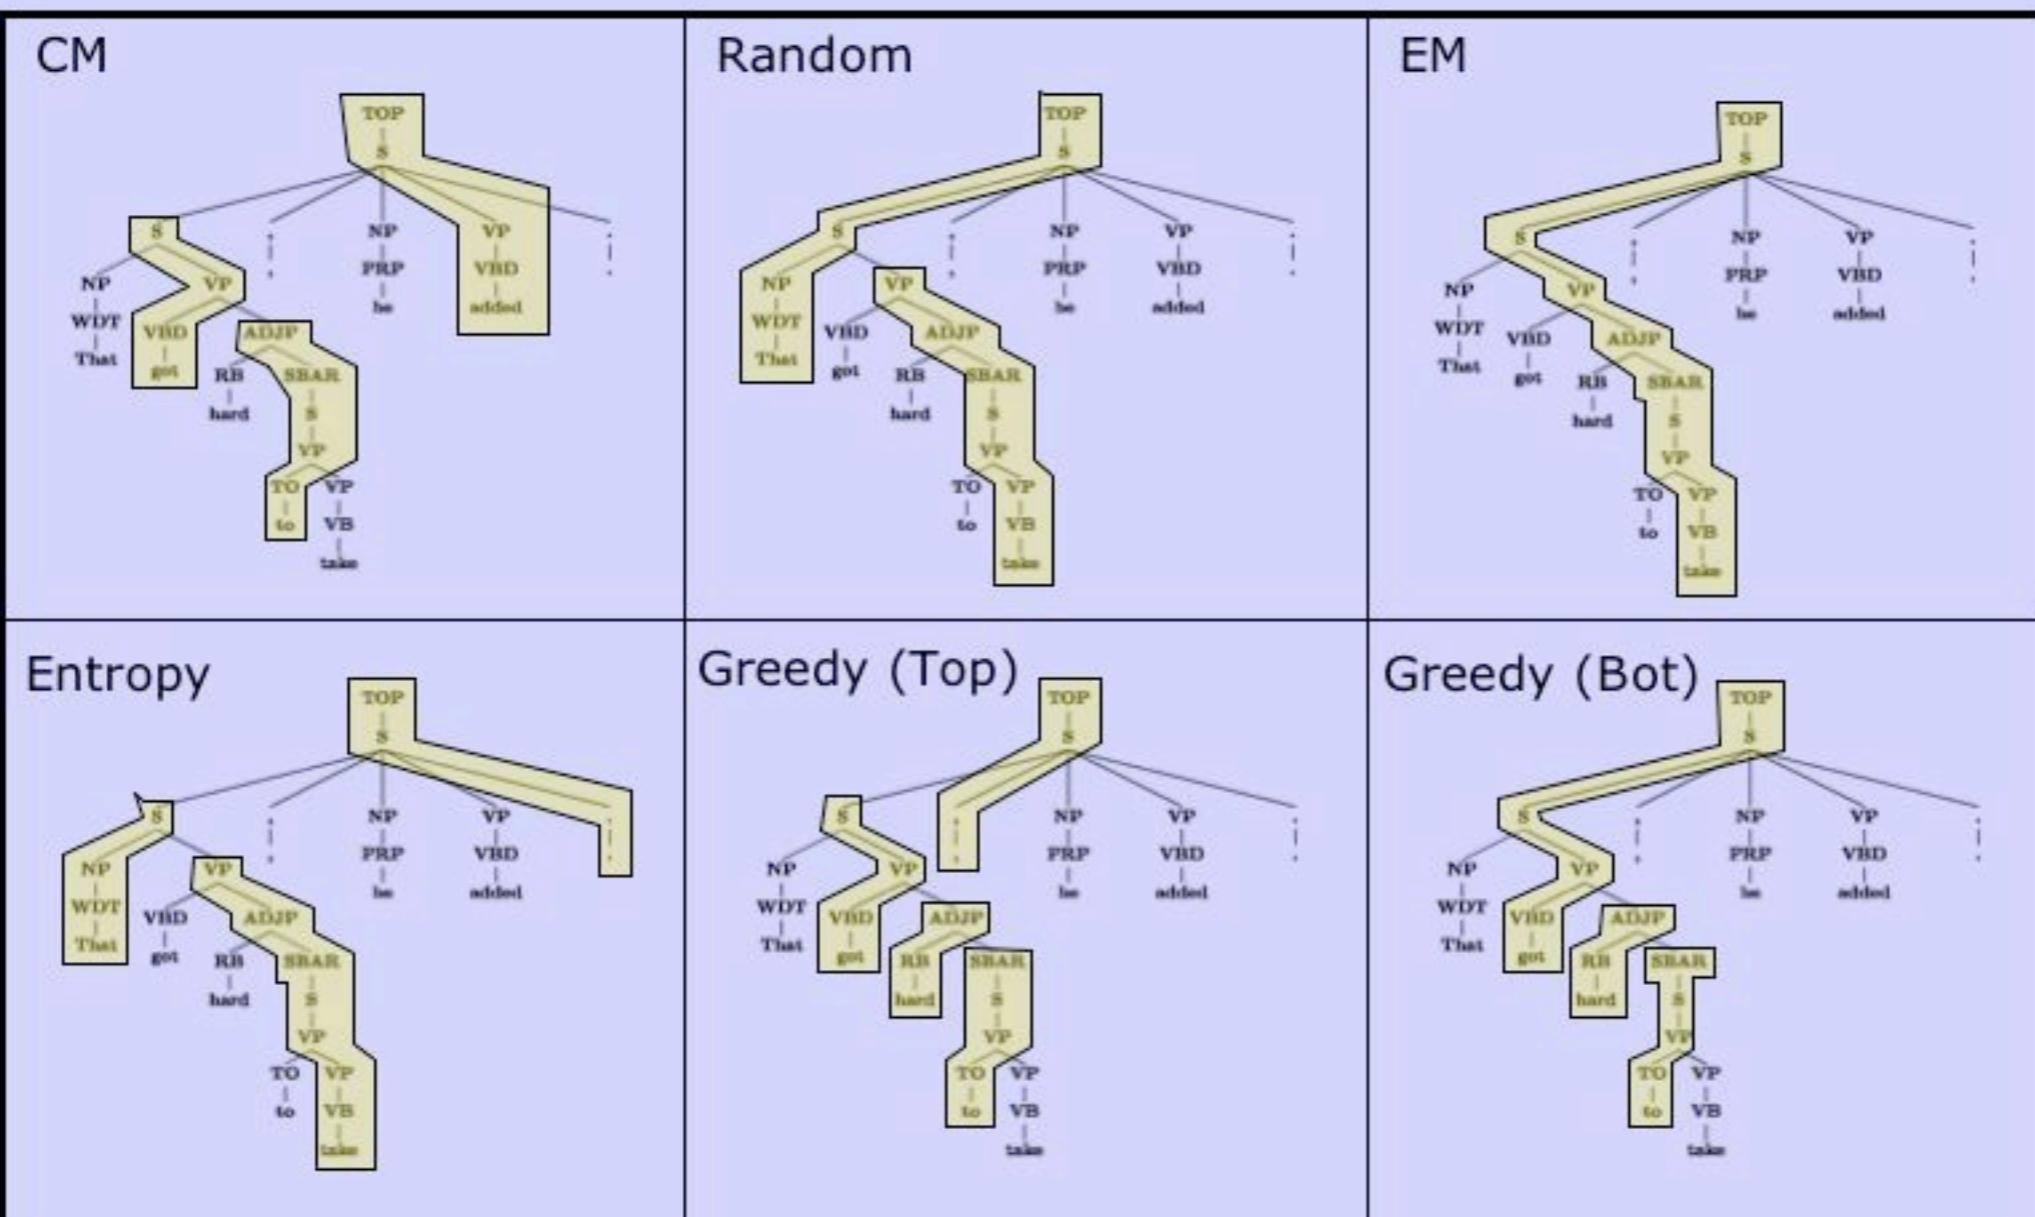

$$H(\tau_l) = - \sum_{i=1}^n p(\tau_{l_i}) \log_2 p(\tau_{l_i})$$

$$H(T) = \sum_{l=1}^{|\mathcal{L}|} H(\tau_l)$$

# RESULTS

# CONCLUSIONS

- *Results are promising but not state of the art*
- *Many possible LTSG - not all were evaluated*
- *Possible to come up with better head annotations*
- *Make the extracted fragment more general*
